ABSTRACT

A phone book is a collection of the data required to contact certain individuals such as their name, phone numbers, address, email, etc. We have created a virtual phone book using Python. The user has to input the data in the various fields present and the project converts them into a list. Graphical User Interface has been added using Tkinter and various concepts such as importing functions from another file, timestamp, etc., have been used. The project was made using PyCharm and Visual Studio Code.

TABLE OF CONTENTS

INTRODUCTION

Our project is a virtual phonebook, based on the Yellow Pages and physical Telephone Directories that were commonly available. We intend to create a virtual version of the Telephone Directory, containing all possible means of contacting any given person.

The project allows the user to create contacts, modify or delete a particular contact, segregate them into seven different groups, search a specific person based on any detail, and also delete all contacts in one go. All the contacts are stored alphabetically, irrespective of the time they have been added. This has been done to ensure that they are easily readable by a person. The project has a user-friendly interface with easily recognisable icons for visual memory, if they are going to use it on a long-term basis. The application also has a dark mode to light mode switch, where the user can change the colour of the background, font colours, etc., depending on their need and liking. The project also records the timestamp at which the person has been added. This serves as a unique code for each person.

The project upon opening shows a menu containing all the different options. Upon pressing 'Create Contact', the person has to enter the name of the person, at the most three phone numbers, their email, date of birth, address, category, and finally, designation. All of these data will be stored in a nested list.

We first created the basic structure of the project using list and string functions, without any Graphical User Interface. Graphical User Interface was later on added to the project using Tkinter. Tkinter is one of the standard GUI libraries in Python. We have used Tkinter to add the background colour, message boxes, title, buttons, etc.

For the ease of programming and reading source code, we have divided the entire project into 4 different files and we have imported the functions of one file to another in order to access them. The different inbuilt modules used are sys, Datetime, Tkinter, etc.

IMPLEMENTATION

TESTING

We have tested and made sure that there are no logical and syntax errors during the execution of the project. We have added two backgrounds, a Light Mode and a Dark Mode for aesthetic purposes. The user can switch between them anytime. We have tested every function present in the application to make sure that they are all error free. To prevent a person from entering alphabets as the input for phone numbers, we have ensured that the new person's list will get appended only if the phone numbers contain numbers, and not alphabets and special characters.

Every time the user adds a person's details, the person's details are added to the directory and is then displayed when All Contacts is opened. The user can modify a person's details by clicking on their name in in the All-Contacts tab. A person's contact can also be deleted in the same place. The application also allows the user to delete all the contacts present in one go. If the user clicks on Delete All Contacts, every single contact and their details present in the application will be erased.

We have also enabled the user to sort the contacts into different pre-existing groups based on their need. The application provides multiple groups, namely, Family, Friends, Work, Emergency Contacts, etc. We have also added the feature to select a contact as an Important Contact or a Favourite Contact.

One of the main features of the application is its ability to search for a contact. It allows them to search for specific contacts based on any criteria, be it their name, phone number, email address, address, category, etc. All the contacts are stored in alphabetical order so that they can be easily accessed. Each contact also stores the timestamp at which they have been added. This serves as a unique ID for each person.

ANALYSIS

The project has been tested to our abilities and we have not found any logical or syntax errors. Based on the reviews, the project has been updated to contain the unique ID generated using the timestamp, the ability to add multiple phone numbers, etc. Extra features such as the Groups, Dark to Light Mode conversion, and many other features have been added to the project. The project also has a Sample Data that has been included for ease of usage during demonstration and testing.

CONCLUSION

We thus conclude out project titled, 'Phonebook", made using Python and using environments such as PyCharm and Visual Studio Code. Phonebook is a user-friendly project that contains Graphical User Interface, which is convenient to a user who does not have any knowledge of coding. GUI has been implemented using Tkinter and many other modules have been utilized for various purposes such as the timestamp, etc. We have also given the user the choice to choose the mode in which they want the program to be displayed, i.e., Light Mode or Dark Mode.

FUTURE ENHANCEMENTS

No project is perfect as we are after all humans and humans are bound to make errors. We believe that our project could be enhanced in the following ways:

1.   The Graphical User Interface could be modified and the colour scheme used could have been enhanced.

2.   The ability to add a person to more than one group, especially to the Favourites and Emergency Contacts groups could be added.

3.   The project could be linked to a database containing the contact information so that the user does not have to input all the data every time they use the application.
